A NEW SPARK COUNTER (USSR)

Bayukov, Yu. D., G. A. Leksin, D. A. Suchkov, and V. V. Telenkov.  
Pribory i tekhnika eksperimenta, no. 2, Mar-Apr 1963, 45-47.

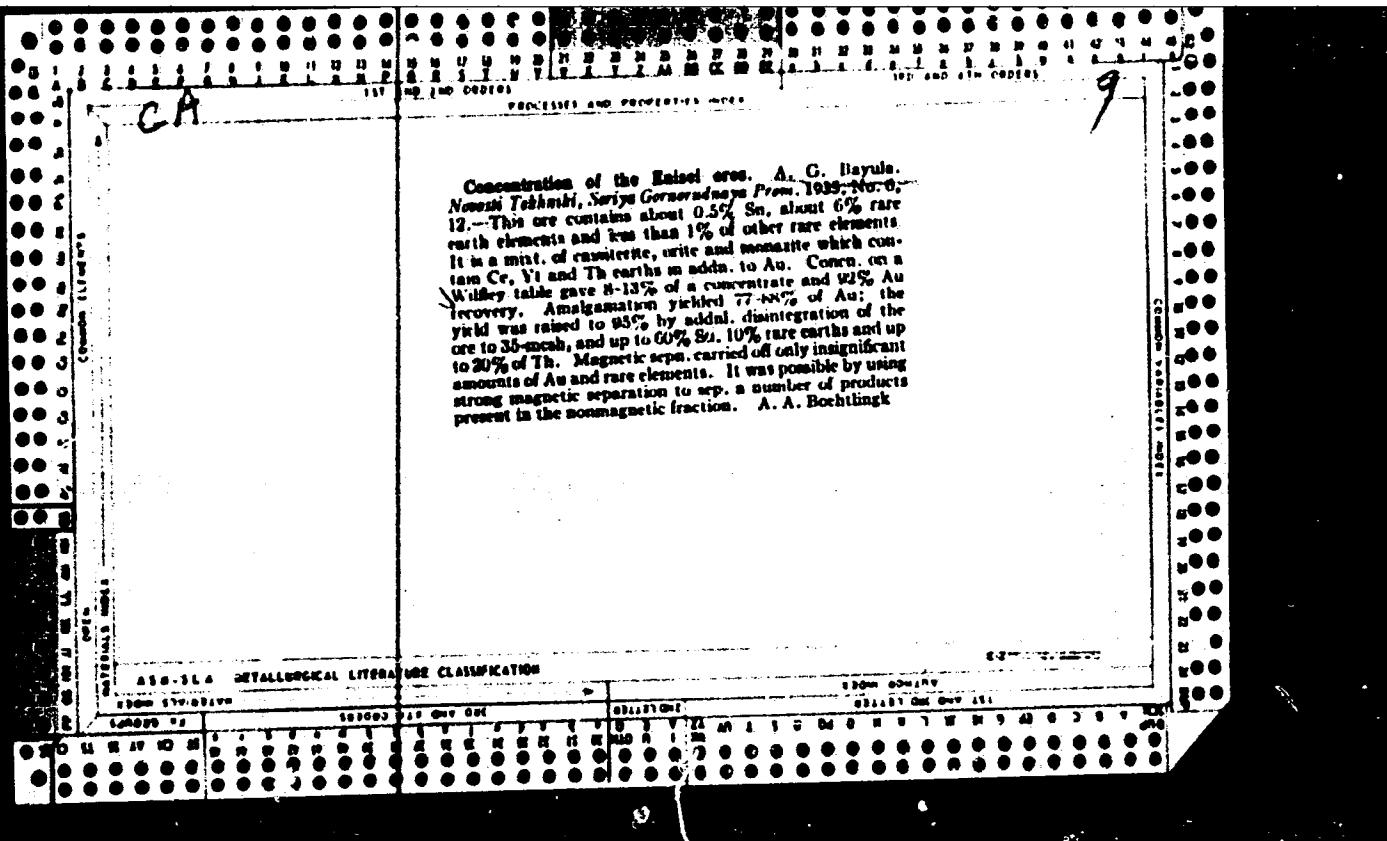

S/120/63/000/002/009/041

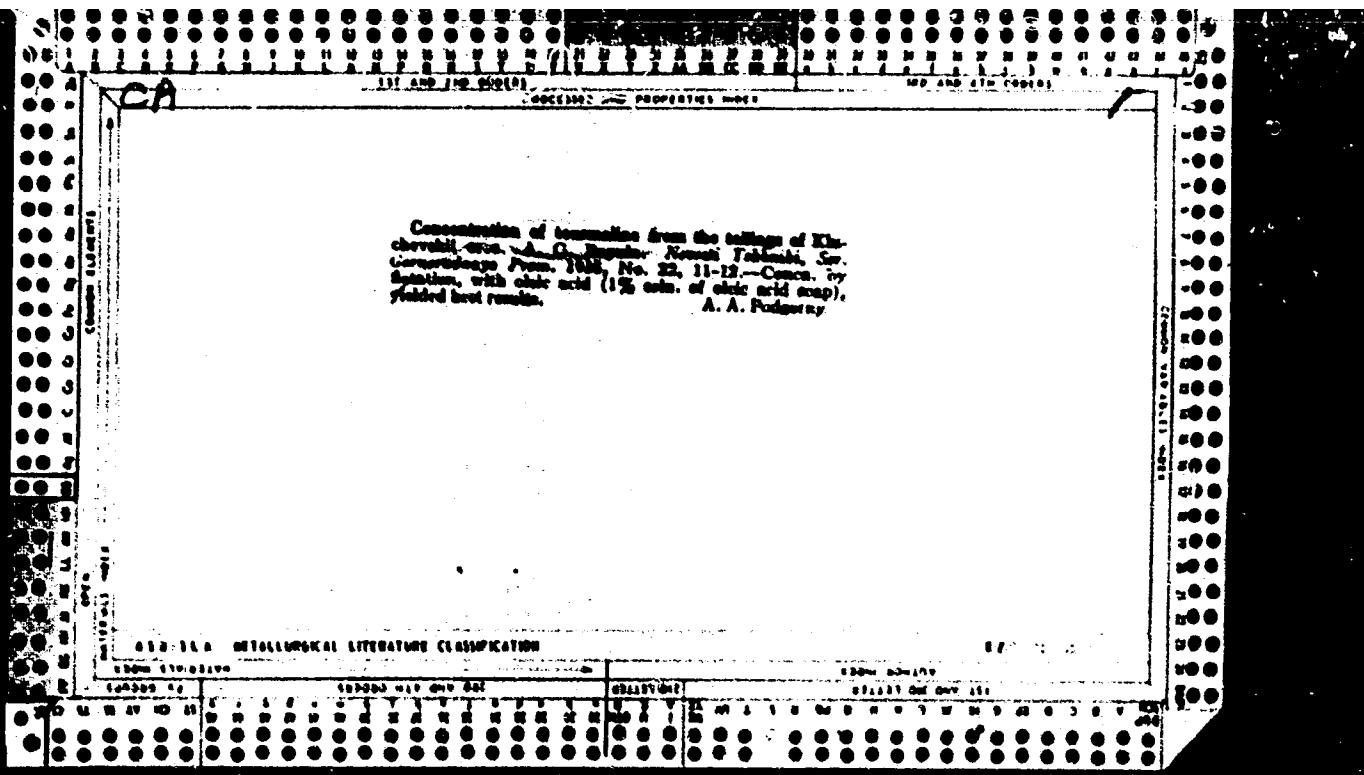

A new spark counter with a high voltage power supply for recording secondary  $\pi$ -mesons generated in the reaction  $\pi^- + p \rightarrow \pi^+ + n$  is described. The counter, characterized by the small amount of matter in the path of the incident particles, consists of 8 electrodes, placed into a cylindrical brass case, forming 4 spark gaps. The electrodes are made of aluminum foil 7  $\mu$  thick stretched between steel rings. The spark counter is evacuated to a pressure of  $10^{-1}$  to  $10^{-3}$  mm Hg and then filled with neon gas until atmospheric pressure is reached. The sparks are photographed in two mutually perpendicular directions. The recovery time for the generator which produces the high-voltage pulses is about 1 sec. [CS]

Extraction of gold from the waste products of metalurgical plants. A. G. Bergels and I. M. Sternin. *Givnno-Obrabotatel*. Zhd. No. 5, 10439 (1966). — The materials treated were: Durasum As dross (I) and Pb slag (II). Comps. of I: limonite 3.0, pyrite 2.3, arsenopyrite 1.5, magnetite 0.8, galena 0.02, sphalerite 0.84, pyrrhotite 0.33, chalcopyrite 0.1, barite 0.08 and covellite 0.01%. 47.2% of the Au is found I, with the sulfides and 3.4% with quartz and the calcination products. I was ground with varying amounts of Durasum sulfide ores (12% sulfides) to stabilize the fines and to sulfidize mechanically the Au particles. The best results were obtained with a mixt. of 200-mesh (70%) contg. 15% of I and 85% of sulfide ore. Reagents used were: sol. glass 0.5, H<sub>2</sub>SO<sub>4</sub> 0.2, pine oil 0.036 kg. per ton. Times of agitation and flotation were 12 and 20 min., resp.;  $\rho_{fl}$  was 7.8. Yields were 14.98% concentrate and 85.02% tailings contg. 81.20 and 19.80% Au, resp. Comps. of II: Pb sol. in acid 0.09, Pb 0.13, silicates and other compounds 0.40%, and traces of under; Cu complex sulfides 0.157, simple sulfides 0.31, oxides and silicates 0.013%; Zn sol. in acid 1.28, silicate 0.40%; barite sol. in HNO<sub>3</sub> 3.72, insol. in HNO<sub>3</sub> 13.08%. The Au is distributed as follows: 12.1% in Pb, 55.8% in mat, 2.1% in barite and traces in slag. Flotation yielded 25.3% concentrate and 74.7% tailings contg. 63 and 33% Au, resp. Reagents used were: Na<sub>2</sub>S 1.4, pine oil 0.19 and Ba carbonate 0.03 kg. per ton. B.Z.K.

Concentration of Siberian gold ores. A. G. Bayula  
and I. M. Sternin. *Gorno-Oborotn. Zhur.* No. 9, 1955  
(1956).--The newly discovered Au ores in Siberia are  
complex. In add. to the Au, many ores contain also  
rare and nonferrous metals. The latter are extd. by  
flotation and gravitation. Some of the more typical ores,  
their comp., methods of treatment and percentages of  
extn. are given.

ASA-11A METALLURGICAL LITERATURE CLASSIFICATION

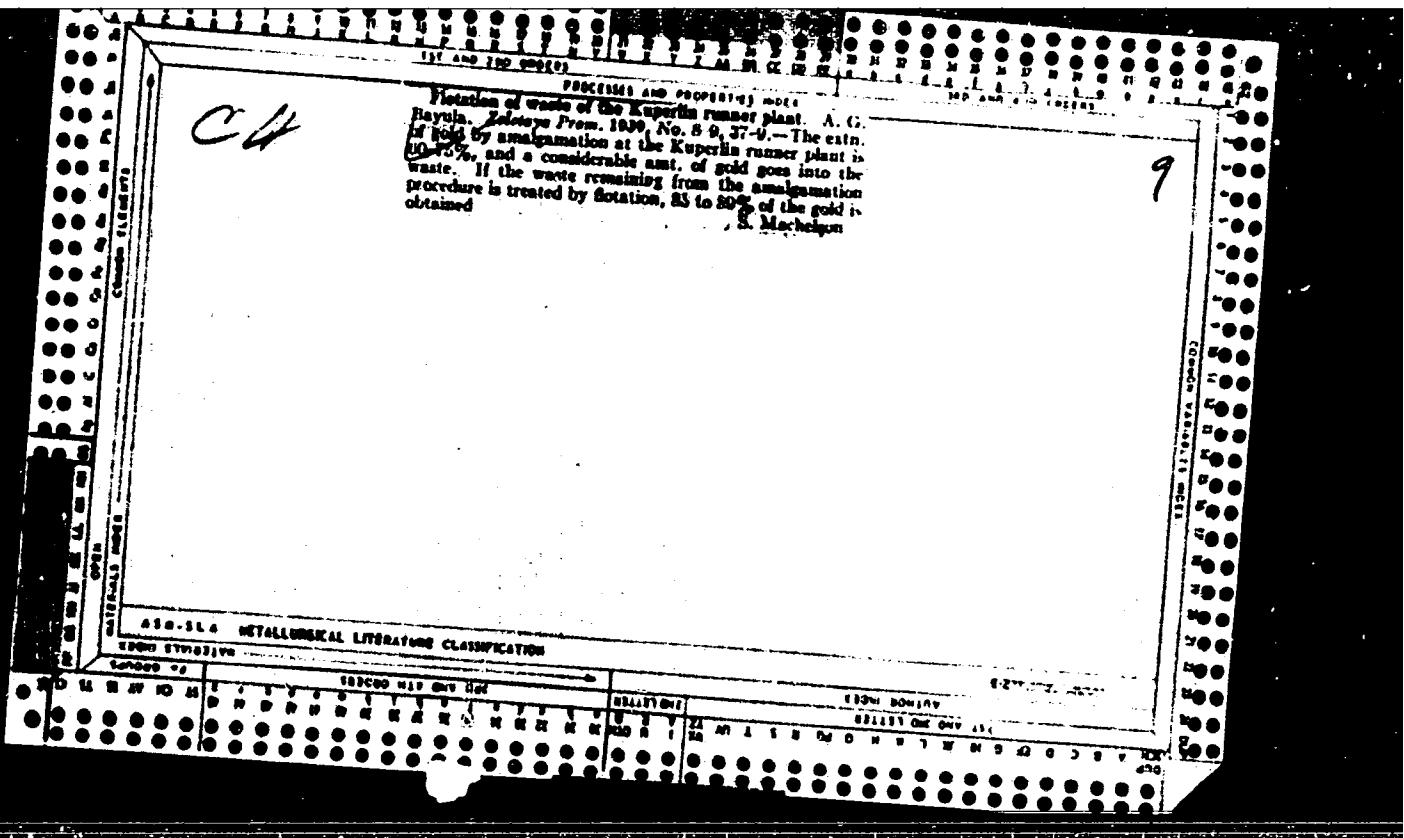

1ST AND 2ND QUARTERS		PROCESSES AND PROPERTIES INDEX												
<p><i>[Signature]</i></p> <p>Rationalizing the concentration of Barabinsk ore. A. G. Rakhlin. (Izv. Akad. Nauk SSSR, No. 1, 20-7 (1937). — The Barabinsk ore-extraction plant commenced operations in 1932, but owing to the lack of detailed knowledge of the ore properties, no definite scheme of ore treatment was adopted. In 1935, a systematic investigation of the Ivanovsk(a) and Andreevsk(b) deposits was started. The mineralogical组成 are: (a) quartz 86.0, carbonaceous shales 9.2, calcite 1.6 and ore complex 3.1%; (b) quartz 88.0, carbonaceous shales 8.7, calcite 2.4 and ore complex 1.9%. The chief component of the ore complex is pyrite. The complete chem. composition are: (a) SiO<sub>2</sub> 60.81, Fe<sub>2</sub>O<sub>3</sub> 1.81, Al<sub>2</sub>O<sub>3</sub> 2.56, CaO 0.89, MgO 0.44, Pb 0.01, Cu 0.04, Zn 0.23, W 0.02, Co 0.0012% and traces of Mo; (b) SiO<sub>2</sub> 91.28, Fe<sub>2</sub>O<sub>3</sub> 1.91, Al<sub>2</sub>O<sub>3</sub> 9.07, CaO 1.02, MgO 0.14, Pb 0.23, Cu 0.04, Zn 0.16, C 0.23, W 0.06, Co 0.0002% and traces of Mo. The Au is dispersed in the sulfides and quartz. Most of the Au in the sulfides is over 0.01 mm. About 90% of the Au in the quartz are freed by grinding to -180-mesh. Extr. of Au was tried by various schemes.</p>		<p>By grinding to -48-mesh, the max. Au extr. was obtained by cyanidation (90-98%) or by the combined scheme of amalgamation—flotation of sulfides and shales—cyanidation (98-100%). Further flotation of shales will remove their harmful effect upon cyanidation and make possible the use of coarser material (-35-mesh), thus increasing the plant's capacity. On the basis of the exptl. results obtained, the following ore-dressing schemes will be tried: (1) Flotation of sulfides and shales with the preliminary retention of the large Au in the closed grinding circuit by using frieze shives, amalgamation, a one-chamber flotation machine of the Denver type or other hydraulic traps. (2) The same as (1) but resorting to cyanidation of the flotation tailings. B. Z. Kamich</p>

Concentration of Artemovsk pyrrhotites. A. G. Meynits.  
Zolotoye /Izv. 11, No. 4-5, 33-40(1939).—Flotation of  
Artemovsk pyrrhotites yielded concentrates contg. 93-95%  
of the Au content of the ore. Conditions of flotation were:  
CaO 0.5-1.0 or soda 2 kg., sol. glass 0.5 kg., xanthate 0.05  
kg. and pine oil 0.010 kg./ton. Duration of agitation

with reagents—12 min., flotation—15 min., liquid/ore ratio  
4:1. The flotation products consist chiefly of sulfides contg. small amts. of Cu, Co, Zn and Au.  $\text{Na}_2\text{SO}_4$   
did not act as a selective depressor of pyrrhotite. With  
lime the extrn. of Au was 93% and with soda 97%.

Pine shavings as a substitute for a frothing agent. A. G. Savula and V. V. Shubina. *Tekhnika Met.* 10, No. 18/19, 36 (1941); *Chem. Zentr.* 1944, II, 1037. *Plotkina*

tests were made with a Au ore in the presence of pine shavings and xanthate but without pine oil. Parallel flotation tests were made with xanthate and pine oil but without the pine shavings. As satisfactory flotation was obtained in the first series of tests as in the second. An abundant froth was obtained with the xanthate and pine shavings. The consumption of shavings was 5 kg. per metric ton of ore. The use of a small amt. of shavings (0.5-1.0 kg./ton) along with the frothing agent reduced the amt. of the latter required and promoted stabilisation of the froth in the presence of small amts. of sulfides in the ore.

TITLE: Determination of tin in materials of high silicic acid content

PERIODICAL: Zavodskaya laboratoriya, v. 28, no. 2, 1962, 166

TEXT: To eliminate the effect of silicic acid, and to lower its adsorption properties, tin is reduced with the twofold excess of metallic aluminum (2 - 4 g of Al for a weighed portion of 1 g). In this case, separation of silicic acid is not necessary. To increase the accuracy of tin titration by iodine, oxygen is kept off by a simple vessel stopper. TITLE: The Problem of Organic Reagents for Osmium ✓

PERIODICAL: Zhurnal analiticheskoy khimii, 1960, Vol. 15, No. 4,  
pp. 505 - 506

TEXT: L. Chugayev (Ref. 1) showed that a red color appears when solutions containing osmium in the form of  $\text{OsO}_4$  or chlorosmate are heated in the presence of thiourea and some drops of HCl, due to the formation of the compound  $[\text{Os}(\text{H}_2\text{N}-\text{CS}-\text{NH}_2)_6] \text{Cl}_3 \cdot \text{H}_2\text{O}$ . Z. Bardoděj (Ref. 5) regards CS as the functional-analytical group for Os and Ru. He found that  $\text{OsO}_4$ , together with  $(\text{H}_2\text{N})_2\text{CS}$ ,  $\text{CS}(\text{NHCH}_3)_2$ , and  $\text{H}_2\text{NCSNNH}_2$ , gives a red color, and with  $\text{H}_2\text{NCSNH}_2$ ,  $\text{CS}(\text{NHCH}_3)_2$ ,  $\text{SC}[\text{N}(\text{CH}_3)_2]_2$ ,  $\text{NH}_4\text{SCN}$ , and  $\text{NaCSN}(\text{C}_2\text{H}_5)_2$  a violet color. The authors aimed at studying the reactions of osmium with two substituted thiourea

derivatives: 4-acetyl amino benzaldehyde thiosemicarbazone (I) and 4-nitrobenzaldehyde semicarbazone (II). Compound I is used for the treatment of tuberculosis, under the name "Tebezón" or TB, Reagent I is used as a 0.1% solution in 1% NaOH, and reagent II, as a 0.05% solution in 1% NaOH. Both solutions are used when still fresh. Under the above-described conditions, osmium, together with reagent I, forms a brown precipitate which dissolves after the addition of ethyl alcohol to a yellow-brown solution whose color depends on the osmium concentration. A red-brown solution results from reagent II after the addition of ethyl alcohol. A perpendicular Pulfrich photometer was used to determine osmium. The maximum optical density was obtained in both cases with the filter M<sub>43</sub> (4360 Å). The results are given in a table and in Figs. 1 and 2. When using reagent I it is possible to determine 1.2 - 14.7 γ Os/ml, and with reagent II, 0.49 - 8.60 γ Os/ml. Both reagents are more sensitive than thiourea which permits the determination of 8 - 40 γ Os/ml. The increase in sensitivity may be explained by the presence of the nitro group causing an increase of the polarity of groups in the para position. There are 2 figures 1 table, and

TITLE: Spectrochronograph with an image converter 25

SOURCE: AN SSSR. Komissiya po nauchnoy fotografii i kinematografii. Uspekhi nauchnoy fotografii, v. 9, 1984. Vysokoskorostnaya fotografiya i kinematografiya (High-speed photography and cinematography), 76-78 and insert facing page 81

TOPIC TAGS: image converter, plasma diagnostics, spectrographic camera

ABSTRACT: Using PIM-type converters with an amplifier, the authors constructed an attachment to mass produce spectrographs for the high speed recording of various portions of the spectrum, i. e., they developed an electron optical spectrochronograph. In order to make the instrument as versatile as possible, a high degree of variation was provided for in camera speed and scanning speed. The resulting complexity of the electronic control circuits required the use of 50 electron tubes, 9 semiconductor triodes, and 62 diodes. The instrument permits the photographing of portions of the spectrum up to 10 mm long at frequencies from 1 thousand to 10 million frames/sec for a total number of frames of 3 to 16 and linear scanning with a time resolution to up  $10^{-9}$  sec. Other features and the operation of the apparatus are described. Experi-

§628. BAYUS <sup>E.</sup> and NIKOLOFF N. \* The importance of myotonography and myotonometry in surgery and traumatology - especially in the evaluation of muscular atrophy

KHIRURGIA (Sofia) 1954, 7/5 (264-272) Graphs 7 illus. 2 (Bulgarian text)

The importance and practical value of myotonographic and myotonometric methods in the evaluation of changes taking place in the muscles are exposed. Two apparatuses, the Sirmay myotonometer and the myotonograph have been employed to this end. The mechanisms as well as the technique in using them are briefly described. This method has served the authors in estimating the state of muscles in atrophy, oedema, endarteritis, after transplantations etc., and has also contributed to building up a correct prognosis, which sometimes was not possible with the clinical data alone.

TITLE: Use of Radioactive Isotopes for the Measurement of Vapor  
Moistness 19

PERIODICAL: Izmeritel'naya tekhnika, 1960, No. 5, pp 50-52

TEXT: A method of measuring vapor moisture is offered here. It bases on the determination of vapor density after absorption of  $\beta$ -particles. A radioactive sulfur isotope was used for the purpose. Investigations were first conducted in the laboratory. Source activity and counter were selected, the optimum distance between isotope and counter as well as the absorption coefficient were determined. The experimental setup shown in Fig. 1 served for the investigations. The setup is briefly described along with the investigation course. An aluminum vessel prepared for the purpose and shown in Fig. 2 was used as source. Radiometer 5-2 (B-2) served as recording device. To determine the vapor density it was necessary to determine the mass absorption coefficient of

Card 1/3

electrons for which no data were found in publications. The mass absorption coefficient  $\mu'$  was first determined in the experimental way in the laboratory as the tangent of the inclination angle of curve

$\ln \frac{I}{I_0} = f(qd)$ .  $I_0$  is the intensity of the electron beam before passing

through the material layer, and  $I$  the intensity after passing through a layer of a thickness  $d$ .  $q$  is the absorber density. In this way,

$\mu' = 197 \text{ cm}^2/\text{g}$  was found for overheated vapor. The vapor density  $q$  was then determined from formula (4). With a view to testing the method described here, the system shown in Fig. 3 was assembled at the Khar'kovskiy turbinnyy zavod (Khar'kov Turbine Works). The section through the measured portion is shown in the same figure and described. In this test,  $\mu' = 200 \text{ cm}^2/\text{g}$  was found for overheated vapor which fits the value obtained in the laboratory. The moisture degree  $\gamma$  was determined from the  $\mu'$  and  $q$  values obtained. It is pointed out in conclusion that the investigations carried out have proven the possibility of measuring the mean moisture in a vapor flow without drawing off,

the disk speed is equivalent to an increase in the gap (by 10 -60%). For a given speed, the above effect is lower for lower magnetic field strength. For a given gap, the effect is higher for higher magnetic field strength. The effect is larger at higher speeds. It is recommended that the induction sensors used in power turbines be calibrated for speed. Orig. art. has: 3 figures, 4 formulas, and 3 tables.

TITLE: Investigation of the two phase medium flow through pipes by observing the attenuation of Beta radiation //

SOURCE: Ref. zh. Elektronika i energetika, Abs. 6G35

REF SOURCE: Vestn. Khar'kovsk. politekhn. in-ta, no. 2(50), 1965, 91-96

TOPIC TAGS: pipe flow, flow analysis, flow characteristic, beta radiation

ABSTRACT: The flow of wet steam was studied by directing a narrow beam of  $\beta$ -radiation through the cross section of a pipe. The source of radiation and the radiation receiver were placed on the opposite sides of the steam pipe directly on its inner walls. The water film thickness on the pipe surfaces was determined by comparing the calculated absorber surface density with the density found by radiation attenuation. According to the experimental data, the film thickness is a function of pressure and water content of the steam and is independent of the steam velocity. [Translation of abstract] M. Vinogradov

TITLE: Photon emission during annihilation of heavy particles

SOURCE: Yadernaya fizika, v. 2, no. 2, 1965, 287-293

TOPIC TAGS: particle annihilation, heavy particle, fermion, photo emission, strong nuclear interaction

ABSTRACT: The authors study some of the characteristics of photon emission which takes place when a pair of fermions is annihilated into another pair of fermions. It is shown that hard photons are emitted chiefly by the original particles. Photon emission is analyzed in the center-of-mass system for the case of electromagnetic annihilation of a pair of fermions, since this makes the easiest example for tracing this type of emission process. Point fermions are assumed to be annihilated into an electron-positron pair. It is shown that the appearance of a peak in the cross section of the radiation by the original particles may be interpreted as conversion of a photon into an electron-positron pair during two-quantum annihilation of the pair of original particles. This same phenomenon is then analyzed in the

Card 1/2

L 2754-66

ACCESSION NR: AP5024343

laboratory coordinate system. Formulas are derived for the cross section of the process with regard to strong interactions, since this process may be used for studying the electromagnetic structure of the proton. TITLE: Emission of two photons in electron collisions

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 49, no. 2, 1965,  
661-671

TOPIC TAGS: bremsstrahlung, particle collision, photon emission  
ABSTRACT: This is a continuation of earlier work by the authors (Phys. Lett. v. 13, 355, 1964), in which the cross section for emission of classical quanta was calculated. In the present paper the authors calculate the cross section for double bremsstrahlung in the center-of-mass system of the colliding particles, under the assumption that one of the photons is soft but the other can have arbitrary energy. The electron energy is assumed quite high, so that expansion in powers of the electron emission angle is possible. The principal terms of the expansions are calculated and the correction terms are estimated. The resultant expressions are useful for the calculation of various processes involving photons. By way of an example, the authors calculate to logarithmic accuracy the single-bremsstrahlung cross section for electron-electron or electron-positron collisions. Orig. art. has: 4 figures and 57 formulas.

Orig Pub : Zh. eksperim. i teor. fiziki; 1956, 30, No 2, 317-329

Abstract : The author considered a strong interaction of the symmetrical pseudo-vector type for the nucleon in a pseudo-scalar meson field. The nucleon is considered extended and infinitely heavy. In the calculation of the eigenvalues of the energy of the system it turns out that the two types of excitation that are most probable in the nucleon-mesons system are the creation of free mesons and the transitions to the isobar state. Unlike Part I, where all the calculations were made in the adiabatic approximation, the authors take approximate account of the non-adiabaticity, using perturbation theory. The methods developed by the authors make it possible to calculate the scattering of mesons by nucleons and the electromagnetic constants (anomalous magnetic moments) of the nucleons.

TITLE: A Scheme of Weak Interactions With Neutral Currents

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960,  
Vol. 39, No. 5(11), pp. 1374 - 1380

TEXT: In order to eliminate experimentally forbidden processes from the weak interaction scheme, new prohibitions have been introduced. (e.g., the prohibition of neutral currents by Feynman and Gell-Mann); it is of interest to possess a scheme where, on one side, the class of possible weak interactions can be expanded, while forbidden processes are automatically excluded on the other. Such a scheme has been suggested by Bludman (Ref.3). It contains a number of new processes, and agrees with the known experimental data. Of course, there are other schemes available. This one is employed to examine the behavior of neutral currents introduced into the theory of weak interactions. Strange particles are neglected here. A space of charge of weak interactions is introduced, where the doublets ( $\nu_\mu$ ), ( $\nu_e$ ), and (pn) are studied assuming that

Card 1/3

86913

A Scheme of Weak Interactions With Neutral Currents S/056/60/039/005/030/051  
B006/B077

the weak interaction is invariant with respect to rotations in this space. Lepton-lepton and lepton-nucleon processes, and also nucleon-nucleon scattering are investigated. The scattering and annihilation cross sections due to weak interaction are calculated for collisions with particles of the same type. The Lagrangian of these processes is represented by  $L = L_+ + L_3$ , where  $L_+$  is the ordinary Lagrangian of weak interaction, and  $L_3$  is the new Lagrangian containing the interaction of neutral currents:

$$\begin{aligned} L_3 = & (\bar{p}p)(\bar{\nu}\nu) - (\bar{n}n)(\bar{\nu}\nu) - \frac{1}{2}(\bar{p}p)(\bar{e}e) + \frac{1}{2}(\bar{n}n)(\bar{e}e) - \frac{1}{2}(\bar{p}p)(\bar{\mu}\mu) \\ & + \frac{1}{2}(\bar{n}n)(\bar{\mu}\mu) + \frac{1}{4}(\bar{p}p)(\bar{p}p) + \frac{1}{4}(\bar{n}n)(\bar{n}n) + (\bar{\nu}\nu)(\bar{\nu}\nu) + \frac{1}{4}(\bar{e}e)(\bar{e}e) \\ & + \frac{1}{4}(\bar{\mu}\mu)(\bar{\mu}\mu) + \frac{1}{2}(\bar{\mu}\mu)(\bar{e}e) - \frac{1}{2}(\bar{p}p)(\bar{n}n) - (\bar{\mu}\mu)(\bar{\nu}\nu) - (\bar{e}e)(\bar{\nu}\nu). \end{aligned}$$

The cross sections are calculated, and the degree of longitudinal polarization in such nucleon-nucleon scattering events is estimated.

The values obtained are  $10^{-6} - 10^{-7}$  at energies of 200-300 Mev; a similar estimate for the lepton-lepton and lepton-nucleon scatterings

TITLE: Electron-electron scattering at large energies

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 40,  
no. 2, 1961, 613-615

TEXT: An approximate calculation of the electron-electron scattering cross section at high initial energies  $E$  and at an angle of scattering  $\theta \gg m/E$  is made in the present paper following a method proposed by A. A. Abrikosov (Ref. 3: ZhETF, 30, 96, 386, 1956). In the determination of the cross section by the method of perturbation it is not possible to restrict oneself to the lowest order because the higher approximations contain the high value  $e^2 \ln^2(E/m)$ . According to a suggestion of Abrikosov, only those terms are taken into account, in which the highest powers of  $e^2 \ln^2(E/m)$  appear. For selecting such terms, certain conditions are formulated. If  $\omega$  is the maximum energy of the emitted photon, the

differential scattering cross section is given by:  $d\sigma = d\sigma_0 \exp\left[-\frac{8e^2}{\pi} \ln \frac{E}{m} \ln \frac{E}{\omega}\right]$ .

Electron-electron scattering...

S/056/61/040/002/033/047  
B112/B214

For  $\omega = E$  this formula goes over into the scattering cross section formula of Möller. The energy distribution of the emitted photons is given by

$$dn(\omega) = \frac{8e^2}{\pi} \frac{d\omega}{\omega} \ln \frac{E}{m}$$

For electrons with the energy  $\epsilon$ , the probability

of energy loss in the interval  $\epsilon \pm d\epsilon$  is

$$dN(\epsilon) = \frac{8e^2}{\pi} \ln \frac{E}{m} \frac{d\epsilon}{\epsilon} \exp \left\{ -\frac{8e^2}{\pi} \ln \frac{E}{m} \ln \frac{E}{\epsilon} \right\}$$

A. A. Abrikosov is thanked for criticizing the paper. There are 1 figure, 1 table, and 3 Soviet-bloc references.

TITLE: Electron-positron interactions at high energies

PERIODICAL: Uspekhi fizicheskikh nauk, v. 78, no. 4, 1962, 619-652

TEXT: The author discusses the most important results of high-energy accelerator experiments on electron-electron collisions and the conclusions from treating these problems by quantum electrodynamics. The results of the most important papers published in this field between 1951 and 1962 are reviewed. The following topics are treated: Head-on collision experiments on electron accelerators; Applicability of quantum electrodynamics at small distances (Calculation of radiative corrections to electrodynamic cross section; radiative corrections in higher perturbation-theoretical approximations; radiative corrections due to strong interactions; phenomenological investigation of the applicability of quantum electrodynamics at small distances); particle production in electron-positron collisions, investigation of structure and cross section of the process (Production of muon pairs; production of pion pairs; processes in which  $\pi^0$ -mesons are involved;

held in 1956. The presence of a field with two directions in an iron-less accelerator with central pushbar permits the acceleration of neutrons toward a nucleus. Thus it is possible to obtain the possible time interval between the two neutrons.

The second method of obtaining the time interval between the two neutrons is to use a magnetic field. A magnetic field can be obtained by using an electric power source. This method is also used in the first method. The second method is also used in the first method. The second method is also used in the first method.

This method is called the "magnetic method". It is also called the "magnetic method".
